ABSTRACT

The invention relates to a structure of a metal spring plate. The opposite edges of a peripheral rim of the metal spring plate are cut straight. The peripheral rim is smoothed out to avoid metal danglers so fatigue fracture due to residual stress won't happen on the metal spring plate after long term wear and tear. Furthermore, a center atop the metal spring plate can be an protrusion or an indentation to enhance feel of response for a cell phone user and to ensure accurate signal input.
